IDA@SMU

Intelligent Data Analysis Lab

Team led by

Margaret H. Dunham

Michael Hahsler

Mission

At IDA@SMU we create novel techniques inspired by knowledge discovery, data mining, machine learning, artificial intelligence and statistical analysis to work with data from various sources.

Current Focus

- Massive data stream modeling: TRACDS™
 - **Hurricane intensity prediction**
 - Effective metagenomic classification for the Human Genome Project
- Recommender systems: R/Apache Mahout

Hurricane Intensity Prediction

“Objective: Improve forecast skill to accuracy and confidence levels required for decision-making and risk management”

NOAA's National Weather Service Strategic Plan 2010-2020

- ❑ Intensity = sustained wind speed
- ❑ Very difficult to predict (rapid intensification)
- ❑ National Hurricane Center uses
 - **Dynamical models:** computational intensive and slow
 - **Statistical models:** *Statistical Hurricane Intensity Prediction Scheme (SHIPS)*

**Path of Hurricane Katrina (2005)
Color shows intensity**

Katrina Facts:

- Category 5 - 175 mph
- Damage: >\$100 billion
- Fatalities: >1,800

PIIH – Prediction Intensity Interval Model for Hurricanes

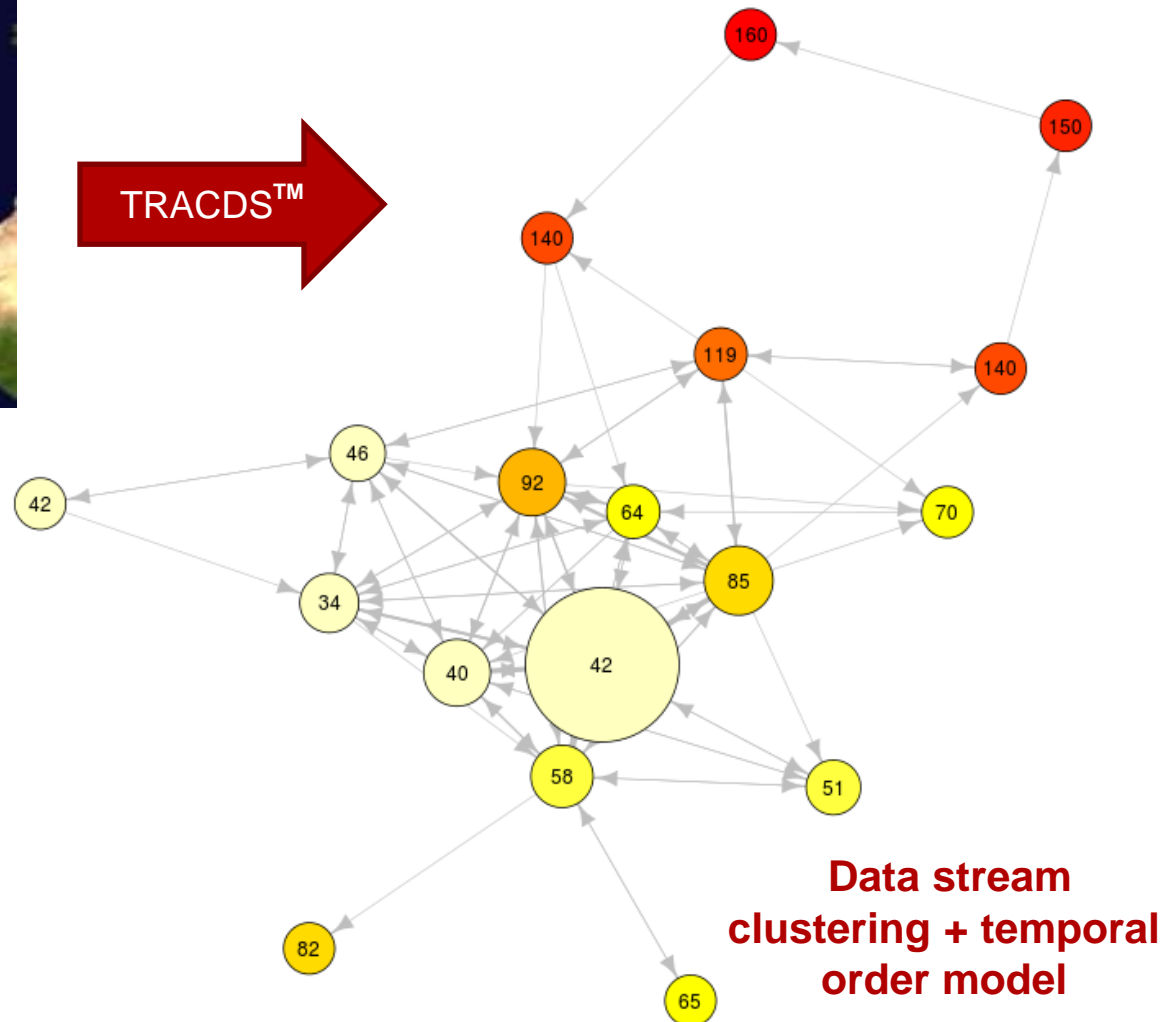

Historic hurricane data

Features

- Current wind speed
- Various temperatures
- Time of the year
- Direction of movement
- GOES Satellite Data (IR)

Currently 23 features from the Statistical Hurricane Intensity Prediction Scheme (SHIPS)

Simplified 1982-2010 PIIH Model

Data stream clustering + temporal order model

Prediction using PIIH – Irene (2011)

Current features of hurricane

Current state of Irene in a simplified 1982-2010 PIIH model

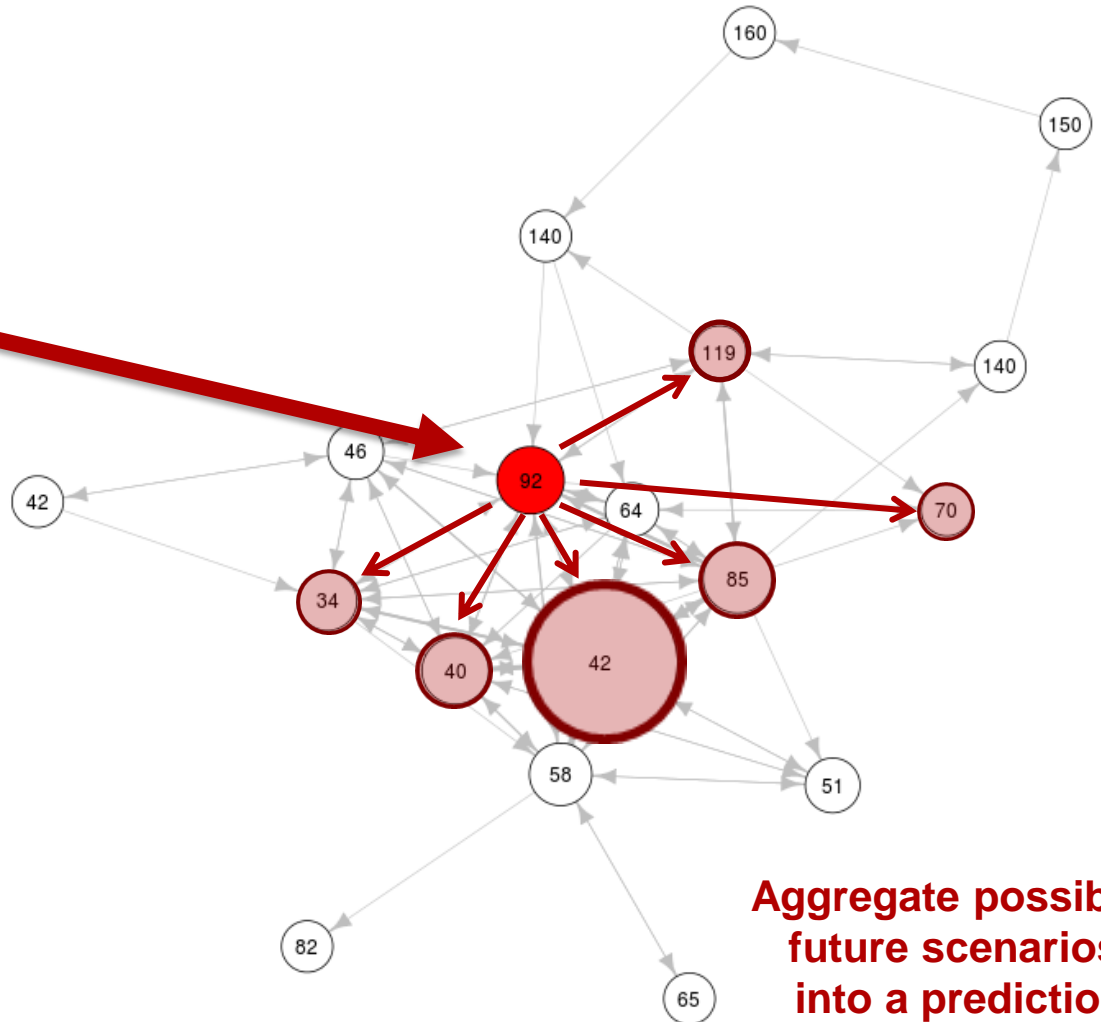

Prediction using PIIH – Irene (2011)

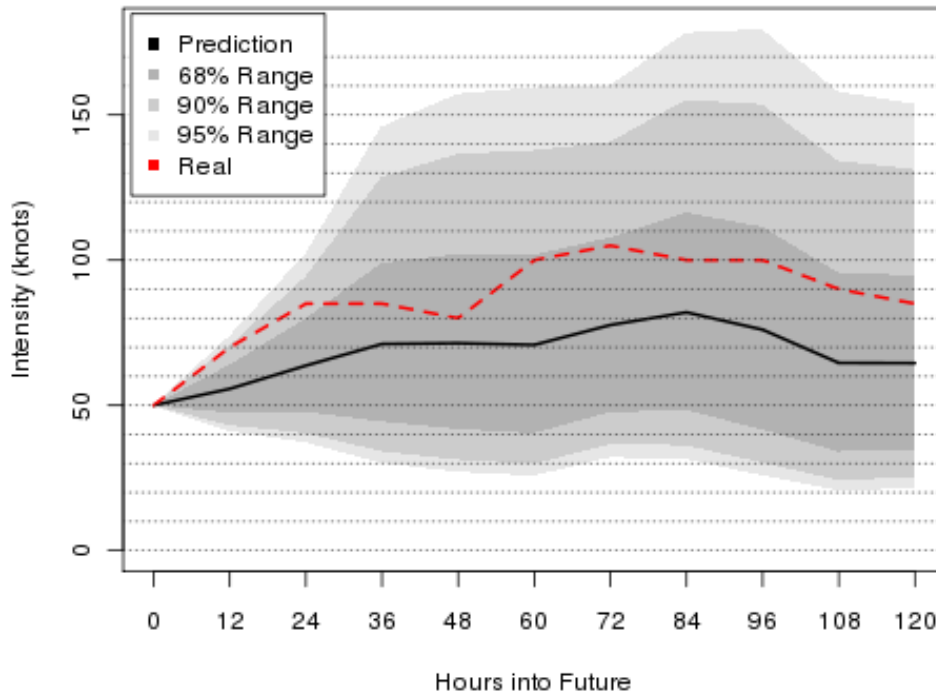

Current features of hurricane

Current state of Irene in a simplified 1982-2010 PIIH model

Prediction Results for Irene (2011)

PIIH Prediction for AL092011 (2011-08-22 00:00 GMT)

	MAD	MSE
PIIH	14.28	310.79
SHIFOR 5*	12.64	229.49
LGEM	15.06	411.73
SHIPS	14.80	319.64
D-SHIPS	17.11	500.36

MAD ... Mean average deviation

MSE ... Mean squared error

* Baseline model

Devastation in New Orleans after Hurricane Katrina in 2005. A new modelling technique may be able to forecast the intensity of an approaching storm. Photograph: Mario Tama/Getty Images

Researchers at the Southern Methodist University in Dallas, Texas are developing a new modelling technique to predict the speed of hurricane winds. Known as the Learning Prediction Intensity Interval model, it is based on data mining using an advanced machine learning process. The computer itself works out the pattern of intensity development from a large pool of raw data, unlike existing methods where humans cherry-pick the most relevant historical data for a regression model to fit the current situation.

Current predictions just give one figure for wind speed, with an error range of about 15mph per day ahead. The new method gives the range of wind speeds (say, 50 to 70 knots), that can be expected with 95% certainty, and the ranges expected with 90% and 68% probability. The researchers are already putting up live predictions for the 2011 hurricanes as they happen from their current model (ida.lyle.smu.edu/PIIH/). Next year they plan to have a fully operational version.

Future Work

1. Deploy model with NOAA

- Add decay model over land
- Evaluate additional features
- Predict rapid intensification
- Interface with NOAA's systems

2. Improve the TRACDS™ model

- Data stream clustering
- Higher-order effects
- Improve model selection and outlier handling

Possible collaboration with
research team at
Watson Research Center

Thank you!
